Control of pain and other symptoms

No patient should die in pain or with other treatable symptoms. Indeed, before social, psychosocial and spiritual problems can be properly addressed, good symptom control must first be achieved: it is difficult to contemplate spiritual issues or to reflect on life’s accomplishments when in pain or with kidney basin in hand. The under-treatment of pain and other symptoms is well documented, but aside from inadequate training of health professionals, the causes are complicated and not well understood. On occasion, physicians may be concerned about balancing good symptom control with the risk of hastening death. Guidelines have been developed to assist physicians in distinguishing appropriate analgesia from euthanasia by lethal injection. Controlling other symptoms, such as nausea, fatigue and breathlessness, may be even more challenging than controlling pain, but effective approaches have been developed.

Physicians must keep in mind that the problems of dying patients have their genesis at an earlier time in the trajectory of illness. Thus, palliative care should not be isolated as simply an end-of-life option; it must be intermeshed with therapies aimed at prolongation of life or cure. As in other areas of medicine, prevention or early control of a symptom is preferable to a rescue attempt on preventable, but now out-of-control, suffering. Every physician who cares for dying patients should ensure that he or she has adequate skills in this domain, as well as access to skilled consultative help from palliative care specialists. A list of leading journals and other information sources is given in the sidebar.

Use of life-sustaining treatments

To the extent possible, the patient and his or her family should be able to choose the site and nature of the care that the patient will receive in the last days of life and should be encouraged to discuss in advance their desires regarding life-sustaining treatments and personal care. Physicians should facilitate this advance care planning and guide and support the patient and the family through the process of giving consent to treatment and arranging for substitute decision-making. A key skill here is the communication of bad news. In addition, physicians need to develop an approach to the opposite problem — when the patient or the family demands treatment that the physician feels is inappropriate. A key skill here is the ability to negotiate a treatment plan that is acceptable to the patient, the family and the health care team.

Support of patients and their families

The support that each patient and his or her family needs from the physician is unique. The best way to find
