

programs, authorized one in the county.

In the space of several months, Indiana has also opened 20 testing sites across the county and set up a “one-stop shop” for various expedited services from across state agencies. These run the gamut “from health insurance enrolment, to birth certificate and ID cards, to mental health and addiction treatment services, so there are no barriers to medical care,” says Pontones.

At last report, the number of new cases has dropped from a peak of 23 a week to a range of 0–3 a week, and the state has yet to spend all \$2.1 million it set aside for the response.

“All levels of government came in full force to put a lid on the Indiana outbreak, and we haven’t seen the same kind of action in Saskatchewan yet, particularly from the federal government,” says Meili.

Loutfy says jurisdictional squabbles remain a major barrier. “There’s this back and forth, ‘That should be a pro-

vincial responsibility,’ or ‘That should be a federal responsibility,’ and all you’re left with is these vulnerable people caught in the middle who aren’t getting adequate care.”

She also cites racism as a factor. “There’s quite a bit towards the Aboriginal community in Saskatchewan,” Loutfy explains. “Without public sympathy, I’m not sure there’s a lot of political interest.”

But it’s also possible that health officials are uncomfortable with the level of paternalism inherent in an emergency response, given the troubled relationship between indigenous Canadians and government.

“We just go with the willingness and readiness of each community,” says Khan. “It doesn’t entirely depend on us. ... The whole partnership has to be ready. That’s what we’re aiming for, and that’s what we’re waiting for.”

David Ironstand of Cote First Nation in southeastern Saskatchewan says that

action is unlikely on some reserves where stigma and ignorance of HIV persist.

He avoided getting tested for years and when he finally learned that he was HIV positive, members of his family cut off contact. “We used to be a family that would always hold one another and kiss one another, but from then on they didn’t do that with me.”

The same attitudes and fears extend to some indigenous leaders, says Ironstand. “It’s the ostrich thing; they’re sticking their heads in the sand and hoping it will go away.”

In August, Ironstand and others will walk more than 300 kilometres from Saskatoon to his reserve near Kamsack, visiting indigenous communities along the way to raise awareness of HIV. “This is my way of getting out there and giving it more of a voice,” he says. — Lauren Vogel, *CMAJ*

Surgical black box may sew up malpractice cases

When an airplane crashes, investigators scramble to locate the black box so they can find out what was happening in the aircraft before the incident. An advance on that technology is now being tested at a Canadian hospital as a means of documenting what happens in an operating room. The question is how will that documentation be used.

Dr. Teodor Grantcharov, Canada Research Chair in Simulation and Surgical Safety at the University of Toronto has been researching the use of a surgical black box for the past year at St. Michael’s Hospital in Toronto. The technology involves several cameras and microphones, along with sensors to document physiological data and key aspects of the environment, such as temperature. Postsurgery the data are assessed by a performance team.

“It allows us to objectively reconstruct what happens,” says Grantcharov.

The intent of the new technology is to enhance health team performance, pinpoint errors and missteps (human and otherwise), and subsequently identify ways to prevent and address those

issues. However, the data in an operating room black box could be used as evidence in medical malpractice suits unless precluded by legislation — in much the same way morbidity and mortality assessments made by hospitals and staff for the purpose of quality assurance and improvements are exempt from being used in court.

Grantcharov would like to see black box data exempted. “This should be protected and not used in court. It should be used to benefit the profession and the safety of patients. It would be wrong to fuel the litigation industry.”

Data recorded by the black box system could well speak for patients unable to speak for themselves because they were under anaesthesia or unfamiliar with hospital procedures and protocol.

However, lawyer Ray Wagner, founder of “Wagners — A Serious Injury Law Firm in Halifax,” says the data could also help surgeons who are being sued. “With the black box, critical procedures and techniques could be objectively assessed by peer surgeons when a poor outcome occurs. From the surgeon’s point of view, the data would be confir-

mation that all was done right but the poor outcome was beyond their control.”

Good medical care includes clear communication and thorough documentation, according to the Canadian Medical Protective Association. Dr. Gordon Wallace, managing director of safe medical care, says “This same documentation is also important for demonstrating the quality of care provided if the care comes into question at a later date.”

Wagner acknowledges the documentation of surgical procedures could add a layer of anxiety to the operating room team. “But,” he points out, “it may eliminate the need for lengthy litigation when the record confirms or denies the accusations of malpractice.”

At present, the use of black box technology at St. Michael’s is in the research stage and all operating room participants must give their consent to being recorded and monitored. Grantcharov says, “Someday, this will be a standard part of an operating room much like a black box is in an airplane today.” — donalee Moulton, Halifax, NS
